# A study on effective inventory management decisions for material required in educational institutes with reference to educational institutes across Pune city 

Jaydeep Ramchandra Kadam<br>Research Scholar, BIMM, Pune<br>Kadamjaydeep7@gmail.com

#### Abstract

Material management function of conservation of materials and their optimum utilization has great importance in overall efficiency of any industry. Inventory management is the soul of materials management aims at optimization of inventory investment to ensure continuity in availability of materials. Inventory management has been one of many analytical aspects of management. This involves optimizing the resources available to store various materials. Lack of inventory may lead to stock-outs, resulting in customer dissatisfaction, opportunity loss. Very high inventory on the other hand may lead to increase in investment and may lead to liquidity death. Thus, inventory optimization should ensure that stocks are neither too low nor too high. It appears that any effort to rationalize inventories can lead to substantial savings. Hence, scientific management of inventory can help in reduction of excessive inventory and hence the investment in inventory.

This paper deals with the study of various materials required by educational institutes for their day to day operations and setting up the effective inventory strategy for these educational institutes with the help of selective control techniques, economic order quantity and by minimization of annual total costs (procurement and inventory carrying cost).

Keywords: Inventory Management, Selective control techniques, Economic order quantity (EOQ), Annual total cost.

## 1. Introduction:

For every organization, inventory management is extremely important. Especially in educational institutes where the size of required material inventory to run an organization is very large, inventory management is extremely important. Over the last 65 years the global literacy rate increased by $4 \%$ every 5 years - from $42 \%$ in 1960 to $86 \%$ in 2015. With rapid
increase in literacy rate, number of educational institutes is also increasing. With this increase in number of educational institutes across the globe, inventory planning for them has become very critical. Regardless of whether you are delivering a performance or products, you need to know where your inventory is and where you are going. As organization's needs grow, they need to increase demand from suppliers. In order for suppliers to have customer's goods, it is necessary to maintain excellent and accurate inventory management. Inventory management is defined as the function responsible for the coordination of planning, sourcing, purchasing, moving, storing and controlling inventories in an optimum manner so as to provide a pre-decided service to the customer at a minimum cost. Optimization of inventory is important as balancing between overstocking and under stocking can save large amount of money for organizations. There are various aspects associated with inventory management such as minimization of ordering costs, minimization of inventory carrying costs, reduction in losses due to overstocking, reduction in losses due to non-availability of material.

## 2. Objectives:

i. To Study the material requirement for day to day operations of educational institutes.
ii. To study and prioritize different category of materials with the help of selective control techniques.
iii. To decide the economic order quantity and number of orders required per year for particular item.
iv. To study the total annual inventory cost and efforts to minimize it.

## 3. Literature Review:

To carry out this research study, firstly we need to understand what are annual total costs, how to compute economic order quantity. Also, we need to understand different selective control techniques.

There are different costs involved in inventory management decisions. The costs affected by company's inventory policy [4] are:
i. Inventory carrying cost
ii. Procurement cost
iii. Setup cost
iv. Stock out cost

Inventory carrying costs are the costs incurred in connection with holding of stocks and they include capital cost, loss due to obsolescence and deterioration, taxes and insurance, storage and holding expenses.

Procurement costs are costs incurred in connection with the replenishment of stocks and they include all costs incurred from raising the purchase order to receiving the order.

Setup costs represent the costs of production stoppage to enable a machine for change over from one job to other and include cost elements like idle time cost, cost of idle wages, foregone profit and cost of work order.

Stock out cost is the cost incurred in the event of non-availability of the item when required.

Figure 1. Inventory costs
There are two major costs associated with any order quantity, procurement cost and Inventory carrying cost. The two costs are diametrically opposite to each other. The right quantity to order will be the one that strikes an optimal balance between these two costs.

When these costs are properly balanced, the total cost becomes minimum and the resultant quantity is termed as economic order quantity.

Let,
Annual consumption of the item (units) $=\mathrm{D}$
Price per unit (Rs) $=C$
Procurement cost per order (Rs) $=\mathrm{S}$
Inventory carrying cost component= i
Order quantity (units) $=\mathrm{q}$
Economic order quantity $=$ q*
Annual procurement cost= No. of orders per year X Procurement cost per order

$$
=\mathrm{DS} / \mathrm{q}
$$

Annual inventory carrying cost= Average inventory investment $X$ inventory carrying cost

$$
=\mathrm{qCi} / 2
$$

Annual total cost $=(\mathrm{DS} / \mathrm{q})+(\mathrm{qCi} / 2)$
Economic order quantity $=\sqrt{ }(2 \mathrm{DS} / \mathrm{Ci})$
Various classification are employed to render selective treatment to different types of materials, each classification emphasizes on particular aspects like cost of item, criticality, lead time, consumption, procurement difficulties.

## A. Mechanism of ABC Analysis

The mechanics of classifying the items into ' A ', ' B ' and ' C ' categories is described in the following steps:
i. Calculate rupee annual issues for each item in inventory by multiplying the unit cost by the number of units issued in a year. It is assumed that the issues and consumption are the same.
ii. Sort all items by rupee annual issues in descending sequence.
iii. Prepare a list from these ranked items showing item no., unit cost, annual units issued and annual rupee value of units issued.
iv. Starting at the top of the list, compute a running total, item-by-item issue value and the rupee consumption value.
v. Compute and print for each item the cumulative percentages for the item count and cumulative annual issue value.
The normal items in most organizations show the following pattern:
a. 5 percent to 10 percent of the items on top account about 70 per cent of the total consumption value. These items are called 'A' class items.
b. 15 percent to 20 percent of items below ' $A$ ' class items account for 20 per cent of the total consumption value. These items are called 'B' items.
c. The remaining number of items account for the balance 15 per cent of the total issue value. These items are called 'C' items.

## 4. Research Methodology:

Inventories required for different educational institutes are different. There are possibilities that items required in one institute may not be required in other institute. We need to select items for analysis in such a way that the selected item should be common requirement for maximum institutes. To carry out this study, we need to consider all these constraints. It
becomes very essential to define the methodology so as all the constraints will get covered and final conclusion can be drawn.

Figure 2. Methodology flowchart

## 5. Data Analysis:

Data analysis includes the data collected from different educational institutes across Pune city. Inventory of items required for day to day operations of all institutes are sorted according to their area of usage and items which are commonly required for most of the institute are taken for the research study.

In present case, the procurement cost, which includes order raising costs, order chasing costs, order in-wording costs, paperwork cost, is found to be 32 Indian rupees. Also, Inventory carrying cost component for stationery items is 0.18 .

Following items are selected for the study.

|  | Total |  |  |  |  |  |  |  |

Comparing the total annual inventory costs, before and after the application of material management techniques, we will be able to find the total cost savings.

Table 4. Annual Total Inventory Costs comparison

| Description | Without Inventory <br> Management | With Inventory <br> Management |
| :--- | :---: | :---: |
| Cost of material | 860020 | 860020 |
| Procurement Cost | 1916.8 | 5299 |
| Inventory carrying Cost | 31491.45 | 5310 |
| Annual total inventory cost | 33408.25 | 10609 |
| Annual Inventory Cost savings | $33408.25-10609=22799.25$ |  |
| Percentage savings | $68.24 \%$ |  |

## 6. Conclusions of the research study:

## A. Selective control technique (ABC Analysis)

Any good stock control system should ensure that each item gets the right amount of attention at the right time. Below are the conclusions that can be drawn from ABC analysis:
i. A class items, account for bulk of the annual usage value and hence must attract utmost attention. B items should be brought under normal control and periodic stocktaking should be done. Little control is required for C items.
ii. A class and $B$ class items require careful and accurate determination of order quantities and order points based on exact requirements.
iii. Safety stock should be less for 'A' class items. The possibility of stock out can be cut down by frequent reviewing and forecasting. A moderate safety stock required for ' $B$ ' class items whereas ' $C$ ' class items should have sufficient safety stock to eliminate progressing and to reduce the possibility of stock outs.

## B. Annual total inventory costs saving by application of EOQ

i. EOQ gives the right quantity of orders at right time. It avoids the excessive stock of items and losses due to stockouts.
ii. Procuring ' A ' and ' B ' class items at economic order quantity considering all possible constraints can reduce substantial amount of inventory cost.
iii. In this case, we saved $68.24 \%$ of total annual inventory cost with application of material management techniques and economic order quantity.
